

# Evolution of High Mass Stars

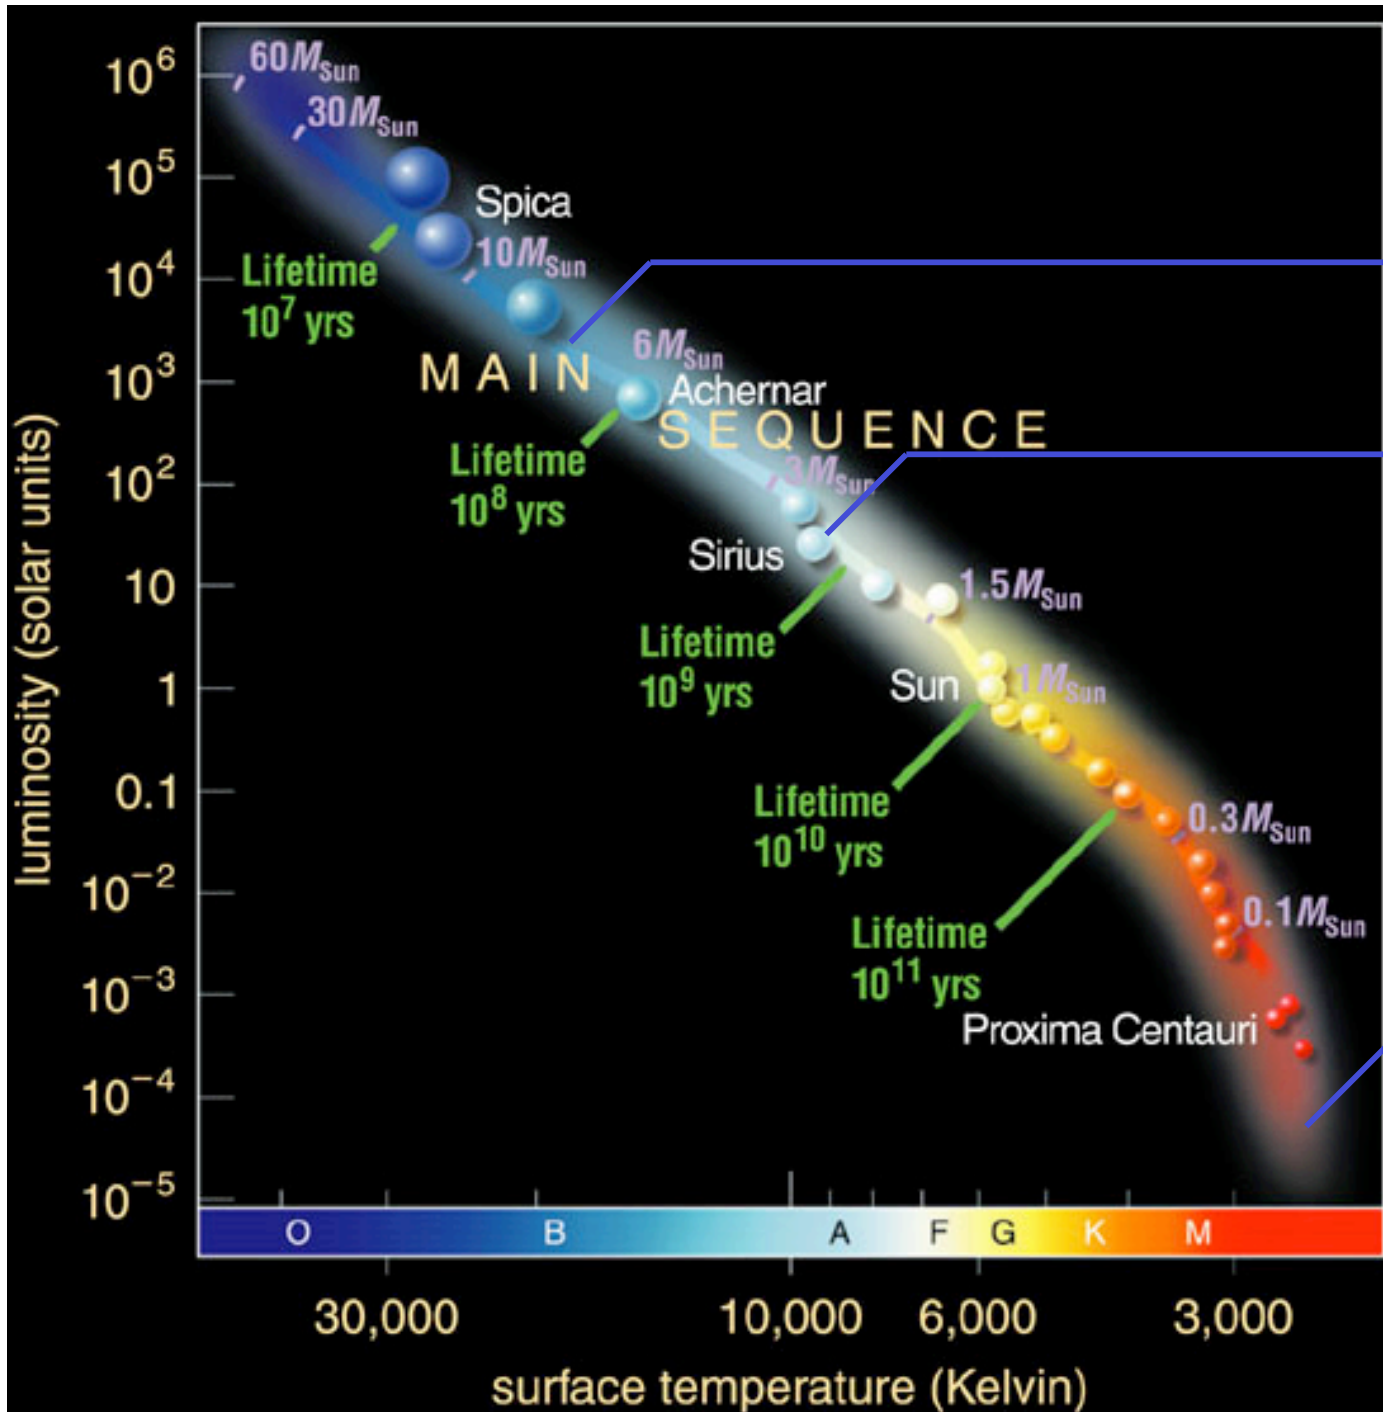

# Stellar Mass and Fusion

- The mass of a main sequence star determines its core pressure and temperature
- Stars of higher mass have higher core temperature and more rapid fusion, making those stars both more luminous and shorter-lived
- Stars of lower mass have cooler cores and slower fusion rates, giving them smaller luminosities and longer lifetimes

**Russel-Vogt Theorem:** *Stellar Mass determines Stellar Evolution*

High-Mass Stars

$> 8 M_{\text{Sun}}$

Intermediate-Mass Stars

Low-Mass Stars

$< 2 M_{\text{Sun}}$

Brown Dwarfs

# What are the life stages of a low-mass star?

# Life Track of a Sun-Like Star

# Life Stages

1. *Protostar*: gravitational contraction
2. Onset of Nuclear Reactions: gravity plus nukes
3. *Main Sequence*:  ${}^1\text{H} \rightarrow {}^4\text{He}$  fusion (p-p chain) in core
4. End of M/S - 10 billion yrs
5. *Red Giant*:  ${}^1\text{H} \rightarrow {}^4\text{He}$  fusion in shell around contracting core (leading to He Flash)
6. *He Main Sequence*: He fusion in core (horizontal branch)  
- 2 billion years
7. Double-shell ( ${}^4\text{He} \rightarrow {}^{12}\text{C}$ ;  ${}^1\text{H} \rightarrow {}^4\text{He}$ ) burning (red giant)
8. Ejection of H and He in a *Planetary Nebula* reveals hot (100,000K) stellar core
9. Leaving behind an inert *White Dwarf* (radiates store of thermal energy)

# Earth's Fate

- Sun's radius will grow to near current radius of Earth's orbit

# Earth's Fate

- Sun's luminosity will rise to 1,000 times its current level—too hot for life on Earth

# High Mass Stars

1.  $L \propto M^3$ ; Fuel  $\propto M$   
 $\Rightarrow$  Lifetime  $\propto 1/M^2$  ( $M/M^3$ )  
*Massive stars live fast, die young*  
(shorter lifetimes in all phases)
2. Higher T  $\Rightarrow$  CNO Cycle on M/S
3. No core degeneracy (higher T  $\Rightarrow$  higher P) means no helium flash
4. Higher T  $\Rightarrow$  more nuclear burning stages (it is the high mass stars that make the elements heavier than C,N,O and even most of the C,N,O that goes into the ISM).
5. Massive stars will have very different evolutionary endpoints (remnants: neutron star or black hole vs white dwarf)

# Life Tracks for Different Masses

- Models show that Sun required about 30 million years to go from protostar to main sequence
- Higher-mass stars form faster
- Lower-mass stars form more slowly

# CNO Cycle

- High-mass main sequence stars fuse H to He at a higher rate using carbon, nitrogen, and oxygen as catalysts
- Greater core temperature enables H nuclei to overcome greater repulsion

# Life Stages of High-Mass Stars

- Late life stages of high-mass stars are similar to those of low-mass stars:
  - Hydrogen core fusion (main sequence)
  - Hydrogen shell burning (supergiant)
  - Helium core fusion (supergiant)
- But continue with further stages:
  - Helium capture
  - Advanced nuclear stages to creation of Iron

# How do high-mass stars make the elements necessary for life?

Helium capture builds C into O, Ne, Mg, ...

# Advanced Nuclear Burning

- Core temperatures in stars with  $>8M_{\text{Sun}}$  allow fusion of elements as heavy as iron

**Key**

12	Atomic number
<b>Mg</b>	Element's symbol
Magnesium	Element's name
24.305	Atomic mass*

\*Atomic masses are fractions because they represent a weighted average of atomic masses of different isotopes—in proportion to the abundance of each isotope on Earth.

Advanced reactions in stars make elements like Si, S, Ca, Fe

# Multiple Shell Burning

- Advanced nuclear burning proceeds in a series of nested shells

Iron is dead end for fusion because nuclear reactions involving iron do not release energy

(Fe has lowest mass per nuclear particle)

Evidence for  
helium  
capture:

Higher  
abundances of  
elements with  
even numbers  
of protons

# Star Clusters and Stellar Lives

- Our knowledge of the life stories of stars comes from comparing mathematical models of stars with observations
- Star clusters are particularly useful because they contain stars of different mass that were born about the same time

Combining models of stars of similar age but different mass helps us to age-date star clusters

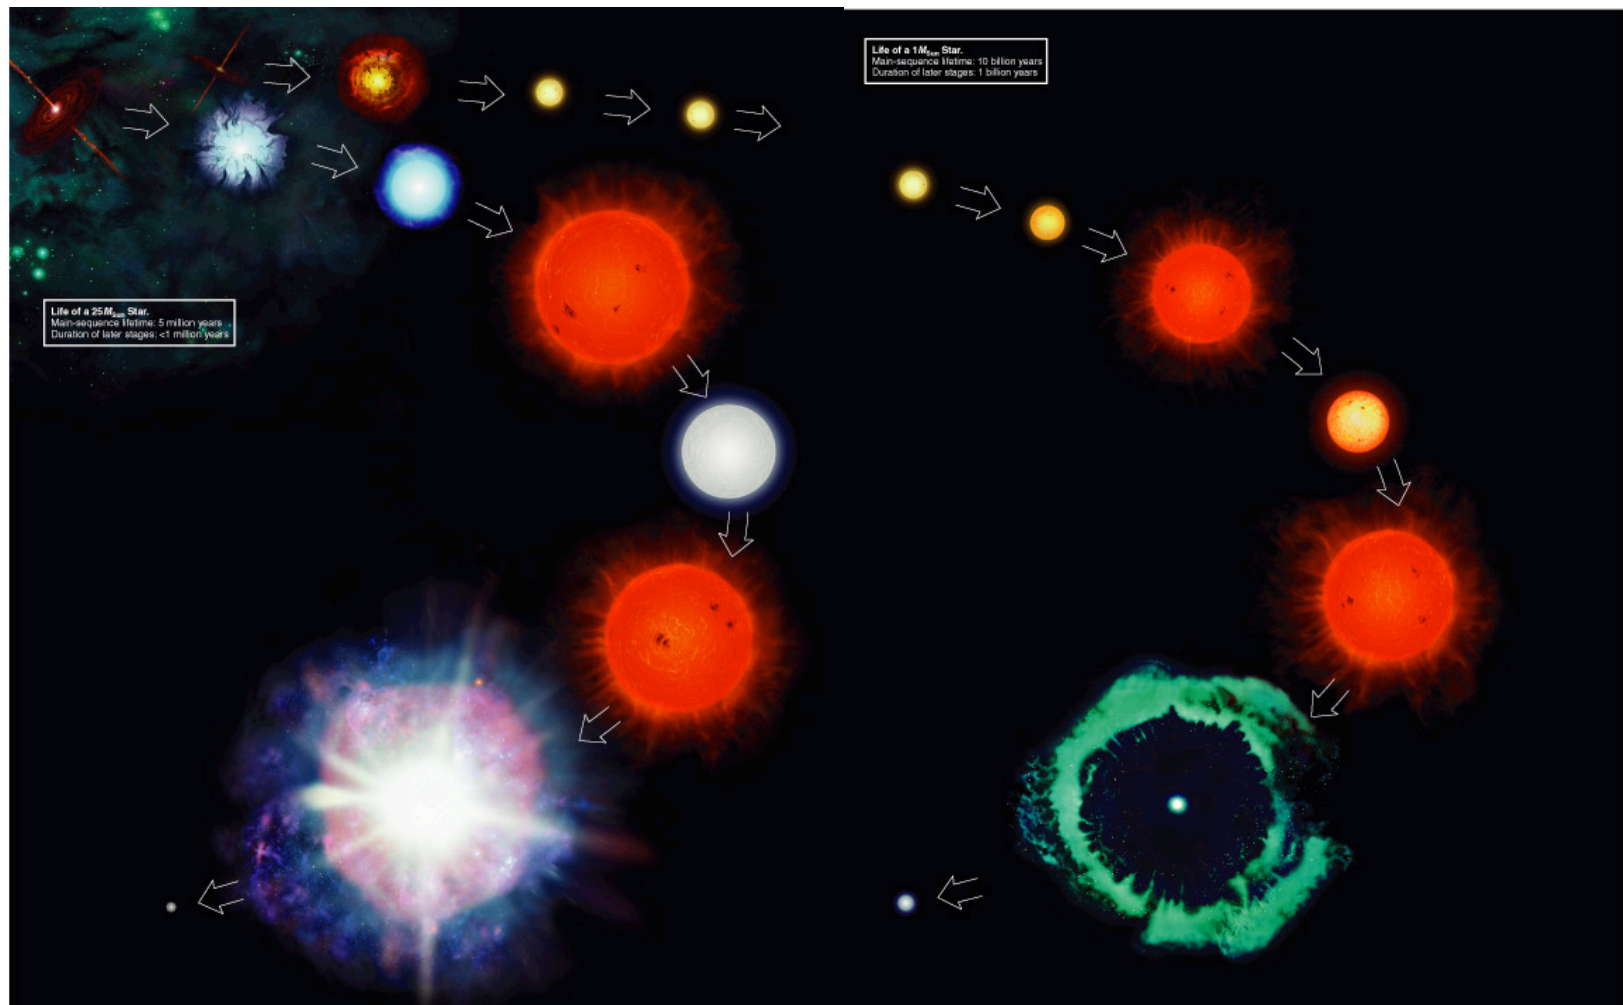

# Life Track after Helium Flash

- Observations of star clusters agree with those models
- Helium-burning stars are found in a *horizontal branch* on the H-R diagram

# How does a star's mass determine its life story?

# Role of Mass

- A star's mass determines its entire life story because it determines its core temperature
- High-mass stars with  $>8M_{\text{Sun}}$  have short lives, eventually becoming hot enough to make iron, and end in supernova explosions
- Low-mass stars with  $<2M_{\text{Sun}}$  have long lives, never become hot enough to fuse carbon nuclei, and end as white dwarfs
- Intermediate mass stars can make elements heavier than carbon but end as white dwarfs

*Not to scale!*

## Low Mass Star Summary

1. Main Sequence: H fuses to He in core
2. Red Giant: H fuses to He in shell around He core
3. Helium Core Burning:  
He fuses to C in core while H fuses to He in shell
4. Double Shell Burning:  
H and He both fuse in shells
5. Planetary Nebula leaves white dwarf behind

*Not to scale!*

## Reasons for Life Stages

- Core shrinks and heats until it's hot enough for fusion
- Nuclei with larger charge require higher temperature for fusion
- Core thermostat is broken while core is not hot enough for fusion (shell burning)
- Core fusion can't happen if degeneracy pressure keeps core from shrinking

# High Mass Star Summary

1. Main Sequence: H fuses to He in core
2. Red Supergiant: H fuses to He in shell around He core
3. Helium Core Burning: He fuses to C in core while H fuses to He in shell
4. Multiple Shell Burning: Many elements fuse in shells
5. Supernova leaves neutron star behind

*Not to scale!*

# What have we learned?

- What are the life stages of a high-mass star?
  - They are similar to the life stages of a low-mass star
- How do high-mass stars make the elements necessary for life?
  - Higher masses produce higher core temperatures that enable fusion of heavier elements
- How does a high-mass star die?
  - Iron core collapses, leading to a supernova

How are the lives of stars with close companions different?

## *Thought Question*

The binary star Algol consists of a  $3.7 M_{\text{Sun}}$  main sequence star and a  $0.8 M_{\text{Sun}}$  subgiant star.

What's strange about this pairing?

How did it come about?

Stars in Algol are close enough that matter can flow from subgiant onto main-sequence star

Star that is now a subgiant was originally more massive

As it reached the end of its life and started to grow, it began to transfer mass to its companion (*mass exchange*)

Now the companion star is more massive

# What have we learned?

- How does a star's mass determine its life story?
  - Mass determines how high a star's core temperature can rise and therefore determines how quickly a star uses its fuel and what kinds of elements it can make
- How are the lives of stars with close companions different?
  - Stars with close companions can exchange mass, altering the usual life stories of stars
